Abstract : *The AI-Powered Nutrition Deficiency Screening and Food Recommendation System is an intelligent healthcare application that uses Artificial Intelligence (AI), Deep Learning, and image processing techniques to identify possible nutritional deficiencies through visual analysis of multiple body features. The proposed system analyzes images of the tongue, fingertips, eyes, and face to identify visible patterns that may be associated with nutritional deficiencies such as Iron, Vitamin, and Protein deficiencies. A Convolutional Neural Network (CNN) is employed to process the collected images, automatically extract important visual features, and classify the input images based on the trained dataset. The system combines information from different body regions to provide a more comprehensive preliminary nutritional screening approach. Based on the predicted deficiency category, the system generates suitable food recommendations to support better dietary habits and nutritional awareness. The proposed system aims to provide a fast, low-cost, and non-invasive approach to preliminary nutrition screening. It can be useful for personal healthcare awareness, fitness monitoring, and rural healthcare support. However, the predictions are intended for preliminary screening and should not replace professional medical diagnosis or laboratory testing.*

Keywords: Artificial Intelligence, Deep Learning, CNN, Nutrition Deficiency Detection, Image Processing, Food Recommendation System.

I. INTRODUCTION

Nutrition plays an important role in maintaining human health, growth, and overall well-being. A balanced diet provides essential nutrients such as iron, vitamins, proteins, and minerals required for the proper functioning of the human body. Nutritional deficiencies occur when the body does not receive sufficient amounts of essential nutrients, which may lead to various health problems, including fatigue, weakness, poor immunity, and other health complications. Early identification of nutritional deficiencies is important for preventing serious health conditions and maintaining a healthy lifestyle.

Traditional methods of detecting nutritional deficiencies generally involve medical examinations and laboratory tests, which may require additional time, cost, and medical facilities. With the development of Artificial Intelligence (AI), Machine Learning, and Deep Learning, image-based analysis has become a promising approach for preliminary health screening. These technologies provide opportunities to analyze visible physical characteristics and identify patterns that may be associated with certain nutritional deficiencies.

The proposed project, AI-Powered Nutrition Deficiency Screening and Food Recommendation System, focuses on analyzing multiple body features, including the tongue, fingertips, eyes, and face, using image processing and Convolutional Neural Networks (CNN). The system collects images of these body regions and processes them to extract important visual features. Deep learning techniques are used to identify patterns that may indicate possible nutritional deficiencies, such as iron, vitamin, and protein deficiencies. Furthermore, the system provides personalized

food recommendations based on the predicted deficiency category. These recommendations aim to improve nutritional awareness and encourage healthy eating habits. By combining multiple image inputs with artificial intelligence, the proposed system aims to provide a convenient, low-cost, and non-invasive preliminary screening approach.

The main objective of this project is to develop an intelligent system that integrates image classification and food recommendation techniques into a single application. It can support personal health awareness, fitness monitoring, and preliminary healthcare assistance, particularly in areas where access to healthcare facilities is limited. However, the system is intended for preliminary screening and does not replace professional medical diagnosis or laboratory testing.

II. METHODOLOGY

The proposed AI-Powered Nutrition Deficiency Screening and Food Recommendation System uses Artificial Intelligence, Deep Learning, and image processing techniques to identify possible nutritional deficiencies through the analysis of tongue, fingertips, eyes, and facial images. The methodology consists of several stages, including dataset collection, image preprocessing, feature extraction, CNN model development, deficiency classification, and food recommendation. The system processes the collected images and identifies visual patterns that may be associated with nutritional deficiencies such as iron, vitamin, and protein deficiencies. Based on the classification results, suitable food recommendations are provided to promote nutritional awareness and healthy eating habits.

A. Dataset Collection

The first stage involves collecting image datasets of different body regions, including the tongue, fingertips, eyes, and face. These datasets are used to train and evaluate the deep learning model. The collected images are organized into appropriate folders according to their respective categories. Proper dataset organization helps the model learn different visual patterns and improves the efficiency of the training process.

B. Image Preprocessing

Image preprocessing is an important step in preparing input images for the classification process. The collected images may have different dimensions, resolutions, and lighting conditions. Therefore, preprocessing techniques are applied to maintain consistency in the input data.

The preprocessing steps include:

1. **Image Loading**: Images are loaded from the collected datasets.
2. **Image Resizing:** All images are resized into a uniform dimension.
3. **Image Normalization:** Pixel values are normalized to improve model training.
4. **Data Augmentation:** Techniques such as rotation, flipping, and zooming may be applied to increase image diversity.
5. **Dataset Splitting:** The images are divided into training, validation, and testing datasets.

C. Feature Extraction Using CNN

A Convolutional Neural Network (CNN) is used to automatically extract important visual features from the input images. The CNN analyzes the tongue, fingertips, eyes, and facial regions to identify patterns and characteristics present in the images. The convolutional layers extract visual features, while pooling layers reduce the dimensionality of the feature maps. The extracted features are passed through fully connected layers to learn the relationships between image features and their corresponding classification categories.

D. Nutritional Deficiency Classification

After feature extraction, the trained CNN model performs image classification to identify possible visual indicators associated with nutritional deficiencies. The system analyzes the input images and generates predicted categories based on the patterns learned from the training dataset.

Impact Factor: 8.2

The classification process focuses on possible indicators associated with iron, vitamin, and protein deficiencies. The predicted category is then passed to the food recommendation module for further processing.

E. Food Recommendation System

The food recommendation module provides suitable food suggestions based on the predicted nutritional deficiency category. A predefined food recommendation database is used to associate different deficiency categories with appropriate nutrient-rich food items.

For example:

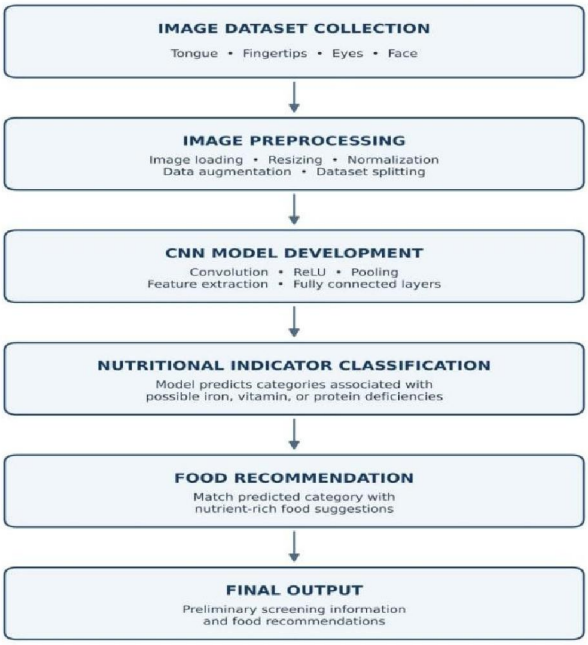
- Iron Deficiency: Spinach, lentils, beans, and other iron-rich foods.
- Vitamin Deficiency: Fruits, vegetables, citrus fruits, and other vitamin-rich foods.
- Protein Deficiency: Eggs, milk, pulses, beans, and nuts.

The recommendations are intended to improve nutritional awareness and encourage balanced dietary habits. They are general suggestions and do not replace personalized medical or dietitian advice.

F. Model Evaluation

The performance of the proposed deep learning model is evaluated using appropriate evaluation metrics such as accuracy, precision, recall, and F1-score. Training and validation accuracy and loss graphs are also analyzed to understand the learning performance of the model.

The evaluation results help determine how effectively the model classifies the input images and identify areas where the system can be improved.



III. MODELING AND ANALYSIS

The proposed AI-Powered Nutrition Deficiency Screening and Food Recommendation System uses Deep Learning and image processing techniques to analyze tongue, fingertips, eyes, and facial images. A Convolutional Neural Network (CNN) is used to extract important image features and classify possible nutritional deficiency categories. Based on the classification results, the system provides suitable food recommendations.

A. Technologies Used

The system is developed using Python, CNN, TensorFlow/Keras, NumPy, and image processing libraries.

B. CNN Model

The CNN model consists of convolutional, pooling, flatten, and fully connected layers. These layers extract visual features from the input images and perform classification.

C. Food Recommendation

Based on the predicted category, the system provides suitable food suggestions for iron, vitamin, and protein deficiencies.

Table 1: Nutritional Deficiency and Food Recommendations

Deficiency	Food Recommendations
Iron	Spinach, lentils, beans
Vitamin	Fruits, carrots, vegetables
Protein	Eggs, milk, nuts, pulses

D. Model Evaluation

The performance of the proposed model is evaluated using accuracy, precision, recall, and F1-score to understand its classification effectiveness.

IV. RESULTS AND DISCUSSION

The results of the proposed AI-Powered Nutritional Deficiency Screening and Food Recommendation Framework are based on the implementation of image-based screening, CNN-based classification, and personalized food recommendation modules. The system supports four image input types: face, tongue, lower conjunctiva, and fingertips. The uploaded or captured images are processed and analyzed to generate screening outputs and corresponding dietary recommendations. The classification performance of each module is evaluated using accuracy, precision, recall, and F1-score. Since each module uses different image characteristics and datasets, the results are evaluated independently.

A. Screening Model Results

The CNN model is used to extract visual features from input images and classify them into predefined screening categories. The face, tongue, conjunctiva, and fingertip modules process their respective images independently. The model performance is assessed using the test dataset of each module.

B. Interpretation

The proposed framework integrates image-based nutritional screening with a food recommendation system to provide nutritional guidance through a unified platform. The CNN-based screening modules analyze images from different anatomical regions, while the recommendation module provides food suggestions based on the predicted screening category and user dietary preferences. The system also includes meal tracking, calorie monitoring, water intake tracking, exercise recording, and progress analytics. These features improve accessibility and support nutritional awareness. However, image-based predictions are preliminary screening outputs and cannot confirm nutritional deficiencies. Clinical validation and laboratory testing are required for reliable medical assessment.

V. CONCLUSION

The development of this project demonstrates how artificial intelligence can be applied to make nutritional information more accessible and easier to understand. By combining image analysis with a food recommendation feature, the system provides users with an initial indication of possible nutrition-related concerns and practical dietary suggestions.

The project also highlights the potential of technology in supporting early nutritional awareness and encouraging healthier food choices. Its effectiveness depends on the quality and diversity of the image dataset and the model's performance. In the future, the system can be enhanced by expanding the dataset, improving prediction reliability, and adding more nutritional categories. Overall, this project serves as a step towards technology-assisted nutrition awareness, rather than a replacement for medical examination or laboratory testing.

ACKNOWLEDGEMENTS

The satisfaction and euphoria that accompany the successful completion of any task would be incomplete without mentioning the people who made it possible, whose constant guidance and encouragement crowned our efforts with success. We express our sincere gratitude to our Principal, Dr Kori Nagaraj, for providing us with the opportunity to carry out our academic project, “AI-Powered Nutritional Deficiency Screening and Food Recommendation Framework.” We wish to place on record our grateful thanks to Dr. H. Girisha, Head of the Department, Computer Science and Engineering, RYMEC, Ballari, for providing encouragement, support, and valuable guidance throughout the completion of this project. We also extend our heartfelt thanks to our project guide, faculty members, and friends for their continuous support, suggestions, and motivation, which helped us successfully complete this project.
