Abstract: *Artificial intelligence is what is referred to as such in English. Artificial intelligence is simply the introduction of experiential learning capabilities similar to those of human intelligence into machines and the software that controls them (Rishikesh Sherlekar). January 14, 2019. Artificial intelligence is used in every industry today thanks to information technology. For instance, banking, railroads, businesses, agriculture, etc. By ordering big machines, the work is done with the aid of computers. In doing this, human labor, money, and time are saved, but at the same time, the speed and quality of work are drastically altered. Artificial intelligence primarily aids in understanding a question or issue and identifying a solution. It involves reasoning, picking up a new skill, and coming up with a solution to a brand-new issue. The first commercial is about using logic, picking up a new skill, and coming up with a fix for a new issue. This change was primarily brought about by the first industrial revolution, which reduced manual labor by substituting machines for it. Previously, people had to operate these machines. However, as information technology has advanced, these machines. It's being handled by computers with a small adjustment Computerized systems appear to be a transformation of human experience and intelligence. If we examine libraries from forty years ago, we discover that the actual library staff handled all the functions of the library, including the collection of books, (cataloging, classification, etc.), book lending, reference services, and other ancillary services. Every service's fine work would not have been possible without the assistance and knowledge of humans.*

Keywords: Libraries
