Abstract: *The convergence of voice recognition technologies and the Internet of Things (IoT) is fundamentally reshaping smart home automation, moving it towards more intuitive and accessible human-machine interfaces. This paper presents the design, implementation, and rigorous evaluation of a robust, cost-effective, voice-controlled home automation system. The proposed system leverages the computational capabilities of the ESP32 microcontroller and integrates seamlessly with major cloud-based voice services, namely Google Assistant and Amazon Alexa. User voice commands are processed by these assistants and routed to the ESP32 via the MQTT (Message Queuing Telemetry Transport) protocol, a lightweight and efficient messaging standard for IoT. The ESP32 acts as the central gateway, interpreting these commands and executing precise control actions on connected home appliances through relay modules. Key advantages of this architecture include its low implementation cost, inherent scalability, secure communication mechanisms, and low-latency operation. Extensive experimental results validate the system's performance, demonstrating an average response time of 0.85 seconds, a command success rate of 98.7%, and a total system power consumption of only 2.5 Watts. These metrics conclusively prove the system's suitability and reliability for real-world, real-time smart home applications.*

Keywords: Voice control, ESP32, IoT, MQTT, Smart home, Home automation, Cloud computing, Embedded Systems

I. INTRODUCTION

The paradigm of home automation has evolved significantly from basic timer-based or remote-controlled systems to intelligent, context-aware environments capable of autonomous decision-making. This transformation is largely driven by the proliferation of the Internet of Things (IoT), which enables everyday physical objects to connect, communicate, and be monitored or controlled remotely via the internet. Concurrently, the advent of sophisticated voice-enabled digital assistants like Google Assistant and Amazon Alexa has introduced a natural and intuitive modality for human-machine interaction. This hands-free control is not only convenient but also profoundly enhances accessibility for elderly users and individuals with different physical abilities.

Traditional home automation systems often rely on manual switches or smartphone applications. While functional, these interfaces lack the intuitive, natural interaction offered by voice control and can be cumbersome in situations where hands-free operation is preferred or necessary. Voice-controlled automation directly addresses these limitations by translating spoken language into actionable digital commands.

The ESP32 microcontroller emerges as an ideal platform for such IoT applications. It is a feature-rich, low-cost system-on-chip (SoC) with integrated Wi-Fi and Bluetooth, providing the necessary connectivity out-of-the-box. Its dual-core processor running at 240 MHz offers substantial computational power for handling network protocols and device logic simultaneously, a significant advantage over simpler microcontrollers. Furthermore, it supports secure communication with cloud services using efficient protocols like MQTT.

This paper contributes a comprehensive design framework for a voice-controlled smart home system, detailing the system architecture, hardware and software configurations, the end-to-end communication flow, and a thorough performance

evaluation. The proposed system is demonstrated to be a practical, efficient, and scalable solution for modern home automation.

II. LITERATURE REVIEW

The domain of IoT-based home automation has been extensively researched, with various studies proposing solutions using different technologies and communication interfaces. A review of relevant literature highlights the evolving trade-offs in this field.

Ahmed et al. [1] (2022) developed a Bluetooth-based automation system using an Arduino Uno. While cost-effective, the system was fundamentally limited by Bluetooth's short operational range (typically <10m) and its inability to efficiently handle multiple concurrent device connections, and it lacked any cloud integration for remote access.

Li and Zhao [2] (2023) proposed a more advanced framework based on a Raspberry Pi, utilizing its Wi-Fi capability to provide a web interface for control. This approach offered greater processing power and a more user-friendly interface. However, the high cost of the Raspberry Pi, its relatively high power consumption, and the complexity of the software setup (often requiring a full Linux OS) make it less ideal for a dedicated, low-cost automation controller.

Kumar et al. [3] (2024) implemented an MQTT-driven solution using a NodeMCU (based on ESP8266). This was a step forward in leveraging IoT protocols for real-time communication. However, the single-core nature of the ESP8266 and its limited processing resources sometimes led to noticeable network delays and performance degradation under heavy load or when managing multiple devices.

Singh et al. [4] (2024) utilized an ESP8266 with the Blynk cloud platform for monitoring and control. While this provided easy cloud integration, the system was constrained by the platform's inherent limitations in terms of customization, scalability, and potential latency introduced by the proprietary cloud infrastructure.

Table 1 shows proposed ESP32-based system is designed to resolve the trade-offs identified in prior work. It combines the low-cost and low-power attributes of the ESP8266 with the superior processing power of a dual-core CPU, integrated Wi-Fi/Bluetooth, and the flexibility of an open-standard MQTT protocol, resulting in a balanced, scalable, and high-performance solution.

Table 1: Comparative Review of Existing Home Automation Systems

Sr. No.	Author(s)	Year	Technology Used	Key Features	Limitations
1	Ahmed et al.	2022	Arduino + Bluetooth	Simple control via phone app	Short range, no cloud link, poor multi-device handling
2	Li & Zhao	2023	Raspberry Pi + Wi-Fi	Powerful processing, web interface	High cost, complex setup, high power consumption
3	Kumar et al.	2024	NodeMCU (ESP8266) + MQTT	Low power, real-time cloud communication	Network delay under load due to constrained processing
4	Singh et al.	2024	ESP8266 + Blynk	Easy cloud monitoring and setup	Limited scalability and customization

III. SYSTEM DESIGN AND ARCHITECTURE

3.1. Architectural Overview

The system follows cloud-edge architecture, designed for reliability and low latency. The core components are the User, the Cloud Services (Voice Assistant and MQTT Broker), and the Edge Device (ESP32 with relays).

Figure 1 shows the data flow from the user's voice command, processed by cloud-based voice assistants, routed via an MQTT broker, and finally executed by the ESP32 controller on the connected appliances.

Figure 1. Block Diagram of the Voice-Controlled Home Automation System

User Interaction: A user issues a voice command, such as "Hey Google, turn on the living room light."

Cloud Processing: The voice command is captured by a smartphone or smart speaker and sent to the respective voice assistant's cloud service (Google Assistant/Alexa). The cloud service performs Automatic Speech Recognition (ASR) and Natural Language Processing (NLP) to convert the audio into a structured text command.

Command Routing via IFTTT & MQTT: A service like IFTTT (If This Then That) is configured to listen for these specific applet triggers from the voice assistant. Upon recognizing a trigger (e.g., "turn_on_living_room_light"), IFTTT acts as a publisher and sends a predefined message to a specific topic (e.g., home/living_room/light) on an MQTT broker (e.g., Adafruit IO, Mosquitto).

Edge Device Action: The ESP32, which is permanently subscribed to the topic home/#, receives the message from the MQTT broker. It parses the message and executes the corresponding function, such as setting a GPIO pin (e.g., GPIO23) to a HIGH or LOW state.

Actuation: The state change on the GPIO pin triggers the connected relay module, which physically switches the AC-powered appliance (e.g., the light) ON or OFF.

3.2. Hardware Components

Table 2: Hardware Components Specification and Function

Component	Specification	Function in the System
ESP32 Dev Module	Dual-core Xtensa LX6 @ 240 MHz, 520KB SRAM, Integrated Wi-Fi (802.11 b/g/n) and Bluetooth 4.2	The central processing unit. Manages Wi-Fi connectivity, runs the MQTT client, parses commands, and controls GPIOs.
4-Channel Relay Module	Opto-isolated, 5V DC control, 10A @ 250V AC switching capability	Provides electrical isolation and acts as a switch to safely control high-voltage AC appliances using low-voltage DC signals from the ESP32.
Power Supply	5V DC, 3A Regulated Adapter	Provides stable power to both the ESP32 and the relay modules. The 3A capacity ensures sufficient current for multiple active relays.
AC Appliances	LED Bulb, Table Fan, Smart Plug	The end devices being controlled. Connected to the mains power supply through the relay contacts.
Voice Assistant Device	Google Nest Mini / Amazon Echo Dot / Smartphone	The input interface for the user, capturing voice commands and initiating the cloud process.

Figure 2 shows detailed circuit diagram showing the ESP32's GPIO pins (GPIO22, GPIO23, etc.) connected to the input pins of the relay module. The relay module is powered separately by the 5V supply, and the AC load (e.g., a lamp) is connected through the relay's Common (COM) and Normally Open (NO) terminals.

Figure 2. Circuit Diagram of ESP32 Interfaced with Relay Module

3.3. System Workflow

Figure 3 shows System Flowchart

Figure 3: System Flowchart

Table 3: Command-to-Action Mapping

Voice Command	Processed Text Command (MQTT Payload)	Action	ESP32 GPIO Pin
"Turn on the light"	light_on	Light ON	GPIO 23 -> HIGH
"Turn off the light"	light_off	Light OFF	GPIO 23 -> LOW
"Turn on the fan"	fan_on	Fan ON	GPIO 22 -> HIGH
"Turn off the fan"	fan_off	Fan OFF	GPIO 22 -> LOW

IV. METHODOLOGY

4.1. Hardware Implementation

The hardware prototype was assembled on a breadboard and later soldered onto a perfboard for stability. The ESP32 DevKit V1 was used as the main controller. A 4-channel 5V relay module was interfaced with the ESP32; the VCC and GND of the module were connected to the 5V power supply, and the control pins (IN1, IN2, etc.) were connected to the ESP32's GPIO pins (e.g., GPIO22, GPIO23), which were configured as digital outputs. The AC components (a 7W LED bulb and a 30W table fan) were connected to the relay's output terminals, ensuring all high-voltage wiring was properly insulated. The entire system was powered by a single 5V/3A DC regulated power adapter.

4.2. Software Implementation

Firmware Development Environment: The ESP32 was programmed using the Arduino IDE, leveraging its extensive library support. The `PubSubClient` library was used for MQTT communication, and the `WiFi` library handled network connectivity.

Wi-Fi Configuration: The firmware includes the SSID and password of the local 2.4 GHz Wi-Fi network. The ESP32 automatically connects to this network on boot.

MQTT Communication Setup: The ESP32 is configured as an MQTT client. It connects to a public MQTT broker (Adafruit IO was used in testing) using a unique Client ID and authentication credentials (username and key). It subscribes to a topic pattern, `home/#`, to listen for all commands for different devices.

IFTTT Applet Configuration: Separate IFTTT applets were created for Google Assistant and each command. For example, a "Turn on the light" voice command trigger was linked to a "Make a web request" action, which published the message `light_on` to the specific MQTT topic feed on Adafruit IO.

Firmware Logic: The core firmware runs a continuous loop where the MQTT client's `loop()` function is called to maintain the connection and check for incoming messages. A callback function is triggered upon message arrival, which compares the topic and payload to determine the required GPIO action.

V. RESULTS AND DISCUSSION

5.1. Experimental Setup

The system prototype was deployed in a standard residential environment (a 10m x 10m room). Testing was conducted over a continuous 48-hour period to assess long-term stability. Two appliances were connected: a 7W LED light and a 30W table fan. Voice commands were issued using Google Assistant on an Android smartphone connected to the same local Wi-Fi network. Network latency and packet loss were monitored using standard network tools.

Figure 4 shows a photograph showing the implemented system with the ESP32, relay module, and connected appliances on a test bench, with wiring clearly visible

Figure 4. Photograph of the Experimental Prototype Setup

5.2. Performance Metrics and Analysis

The system was evaluated against key performance indicators critical for user experience and practical deployment.

Table 4: System Performance Evaluation Results

Parameter	Observed Value	Unit	Remarks / Justification
Average Response Time	0.85	seconds	Measured from the end of the voice command to the physical actuation of the device. This low latency is imperceptible to the user.
Command Success Rate	98.7	%	Out of 500 commands, 6 failed due to temporary Wi-Fi instability and 1 due to an MQTT broker hiccup.
System Power Consumption	2.5	Watts	Measured at the DC power supply input. Includes ESP32 and active relays. Highlights the system's energy efficiency.
Wi-Fi Operating Range	30	meters	Stable connection maintained within a 30m radius from the router in a typical indoor environment with walls.
System Uptime	99.2	%	The system was operational for 99.2% of the 48-hour test, with brief disconnections automatically recovered by the firmware.

A line graph of figure 5 showing that the average response time remains below 1.0 seconds (0.85s to 0.98s) as the number of concurrently connected and monitored devices increases from 1 to 4, demonstrating the ESP32's capable processing power

Figure 5. Graph of Response Time vs Number of Connected Devices

Figure 6 of bar chart illustrating that the command success rate remains above 95% even as simulated network load (packet loss) is increased to 15%, underscoring the robustness of the MQTT protocol and the reconnection logic in the firmware

Figure 6. Graph of Command Success Rate vs Network Load

5.3. Discussion

The experimental results confirm that the proposed system meets the key requirements for a practical smart home automation system. The sub-second response time (0.85s) provides a seamless user experience without perceptible delay. The high success rate (98.7%) indicates reliable communication between all components in the chain. The low power consumption (2.5W) makes it an energy-efficient solution for continuous operation. The ESP32's dual-core architecture proved crucial; one core could handle network stack management (Wi-Fi and MQTT) while the other executed the application logic, preventing the lag and timeout issues observed in single-core solutions like the ESP8266 [3]. The primary limitation observed is the system's complete dependence on an active internet connection. A failure in the cloud service, MQTT broker, or local internet renders the voice control inoperative, though local manual switch control remains possible. The use of IFTTT, while user-friendly, can introduce a single point of failure and adds a small but non-zero latency.

VI. SECURITY AND PRIVACY CONSIDERATIONS

As an IoT system handling user commands, security is paramount. The following measures were implemented to mitigate risks:

MQTT Authentication: The MQTT connection requires a unique Client ID, Username, and a strong Password (or an API Key for brokers like Adafruit IO), preventing unauthorized clients from connecting.

Encryption (TLS): The MQTT client on the ESP32 was configured to use TLS (Transport Layer Security) to encrypt all data in transit between the device and the broker, protecting against eavesdropping and man-in-the-middle attacks.

Cloud-Level Access Control: IFTTT applets are tied to a user's personal account, and the API keys used to publish to the MQTT broker are secret, ensuring that only authorized voice commands can trigger actions.

Data Privacy: The system is designed with a privacy-first approach. Voice data is processed on the secured servers of Google/Amazon and is not stored or processed on the local ESP32. The ESP32 only receives and acts upon pre-processed text commands.

VII. CONCLUSION AND FUTURE SCOPE

7.1. Conclusion

This study has successfully presented the design and implementation of a fully functional, voice-controlled home automation system. By leveraging the powerful and cost-effective ESP32 microcontroller and integrating it with cloud-based voice assistants via the MQTT protocol, the system achieves a high level of performance, reliability, and user-friendliness. The experimental results, including a 0.85-second response time and a 98.7% success rate, validate its effectiveness as a practical solution for modern smart homes. Its low cost and scalability make it an attractive option for both prototyping and real-world deployment.

7.2. Future Scope

To build upon this work, several promising directions for future enhancement are identified:

AI-Driven Predictive Control: Integrating machine learning models on the cloud or at the edge to analyze user habits and sensor data (e.g., temperature, ambient light, occupancy) to automate appliances proactively for energy savings and enhanced comfort.

Offline Voice Recognition: Implementing a limited vocabulary speech recognition engine (e.g., using TensorFlow Lite on ESP32) to handle basic commands during internet outages, increasing system resilience.

Hybrid Cloud-Edge Architecture: Offloading more intelligence to the ESP32 to make local decisions based on sensor inputs, using the cloud only for complex voice commands and long-term logging, thereby reducing latency and cloud dependency.

Multi-Room and Mesh Network Expansion: Developing a system of multiple ESP32 nodes communicating with each other (e.g., using ESP-NOW or Bluetooth Mesh) to create a comprehensive, multi-room automation network controlled by a single central voice interface.
